

Potentials and Pitfalls

Bob Muscarella

Sapienza University, Roma

June 9-11

SDM Course

Course schedule

R exercises ▾

Resources

Intro to SDMs

This short course will include:

- Lectures, readings, and discussions covering basic theory and concepts behind species distribution models (SDMs) and ecological niche models (ENMs)
- Practical experience in acquiring and cleaning species occurrence data, as well as designing, building and evaluating SDM and ENM using a variety of R packages
- Students will gain perspective on the potential applications, strengths, and limitations of SDMs/ENMs

Course participants should have a general understanding of R programming. Participants are welcome (but not required) to join the course with their own data / project ideas. A pre-course reading list and R exercise will be provided after course registration is completed. Questions about the course should be sent to Bob Muscarella robert.muscarella@ebc.uu.se.

Applications of SDMs

(Some) Potential applications of SDMs/ENMs

- Niche structure and limits
- Discovery of species and populations
- Consequences of climate change
- Reconstructing past distributions
- Invasive species applications
- Systematic conservation planning
- Large-scale conservation/restoration projects
- Public health

Niche structure and limits

Abundance-Center Hypothesis:

Species are more abundance towards
the geographic center of the range.

Vol. 124, No. 2

The American Naturalist

August 1984

ON THE RELATIONSHIP BETWEEN ABUNDANCE AND DISTRIBUTION OF SPECIES

JAMES H. BROWN

Department of Ecology and Evolutionary Biology, University of Arizona, Tucson, Arizona 85721

Submitted July 8, 1983; Accepted February 27, 1984

Niche structure and limits

Abundance-Center Hypothesis:

Species are more abundance towards the geographic center of the range.

Mean Density

Scissor-tailed Flycatcher

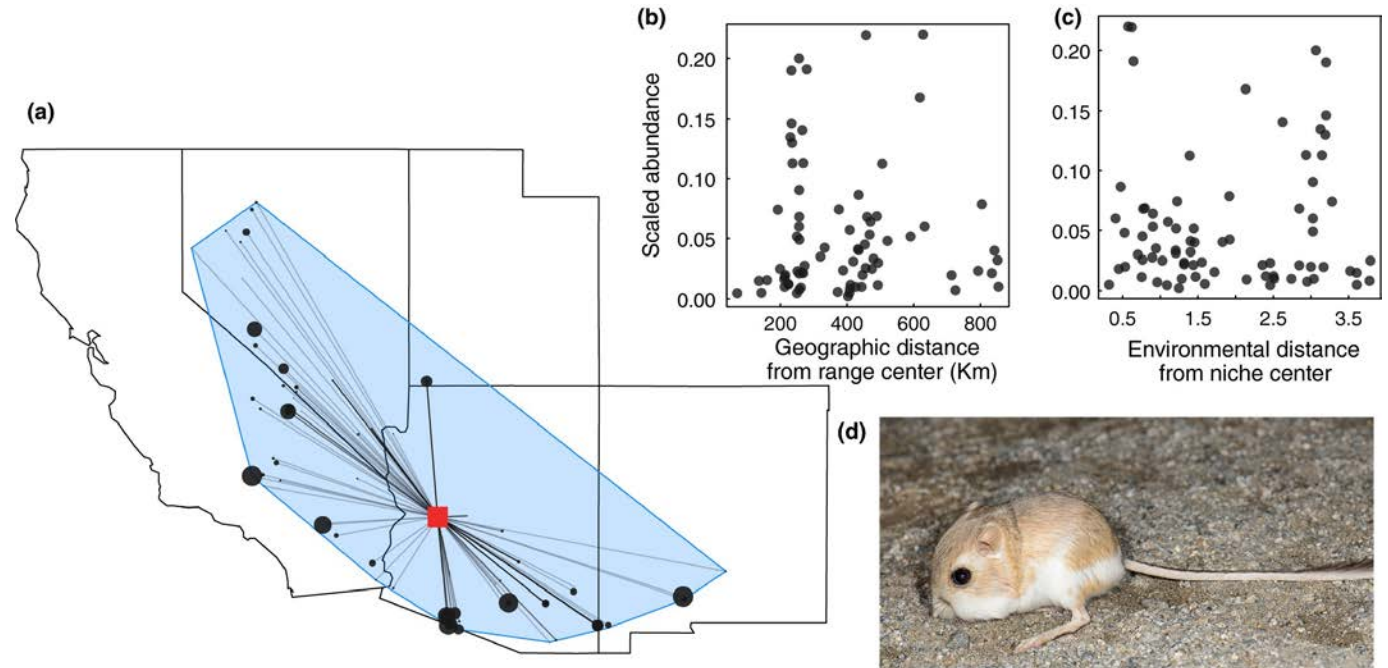

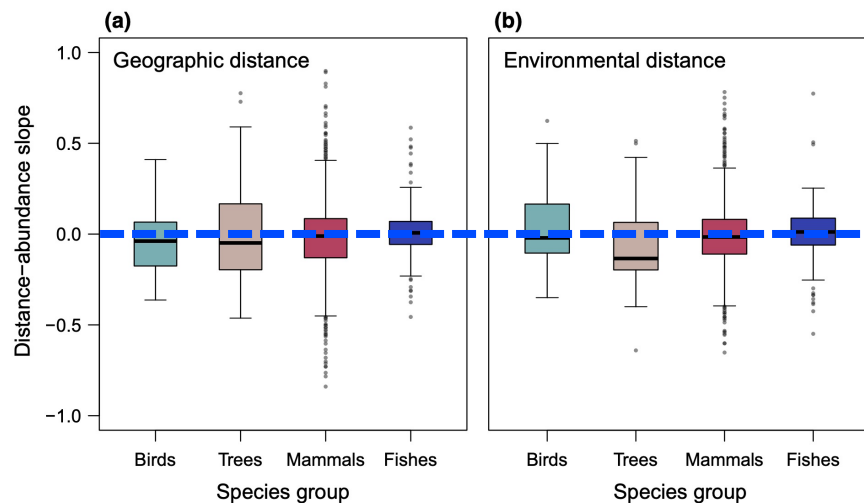

Niche structure and limits

Abundance-Center Hypothesis:

Species are more abundance towards the geographic center of the range.

For >1,400 species of birds, trees, mammals, fishes:

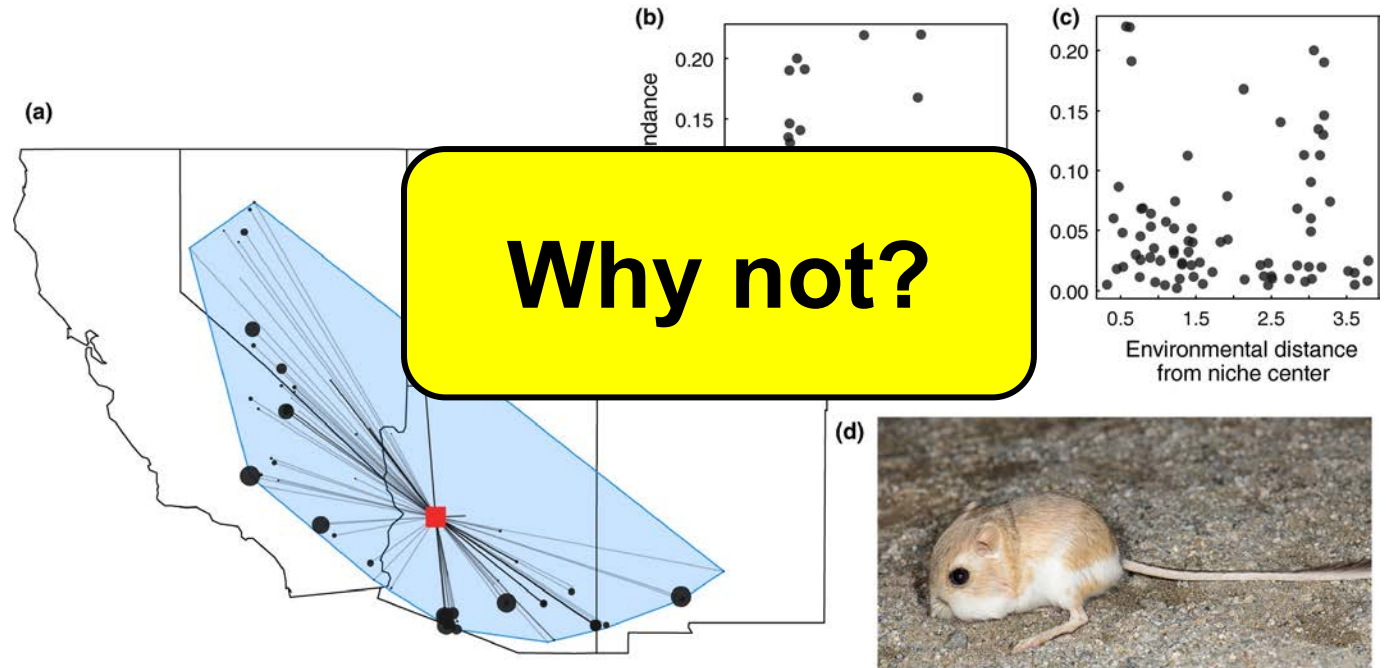

Niche structure and limits

Abundance-Center Hypothesis:

Species are more abundant towards the geographic center of the range.

For >1,400 species of birds, trees, mammals, fishes:

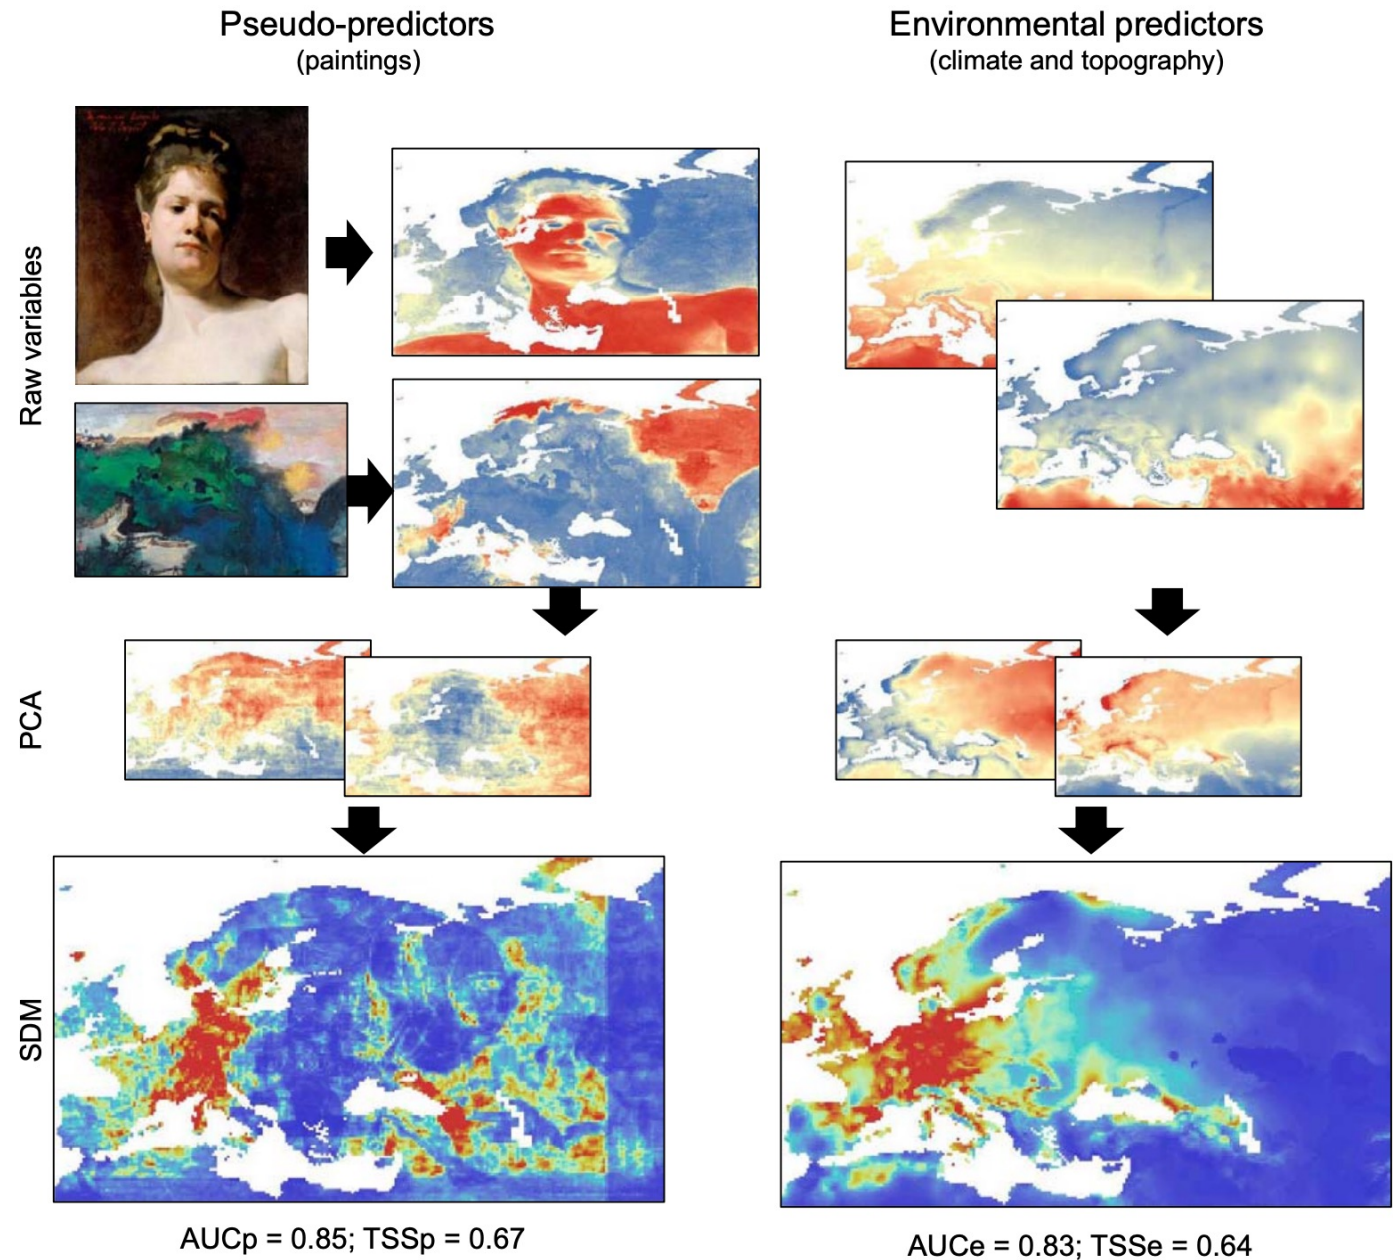

Pitfalls

- Other (unmeasured) variables may be most important determinants of a species distribution

- “Environmental” variables derived from paintings did as good (or better) at predicting species distributions as commonly used bioclimatic variables.
- Metrics of “model performance” do not assess the *biological significance* of SDMs.
- Variable selection *needs* to be hypothesis-driven, connected to the ecology of the study species.

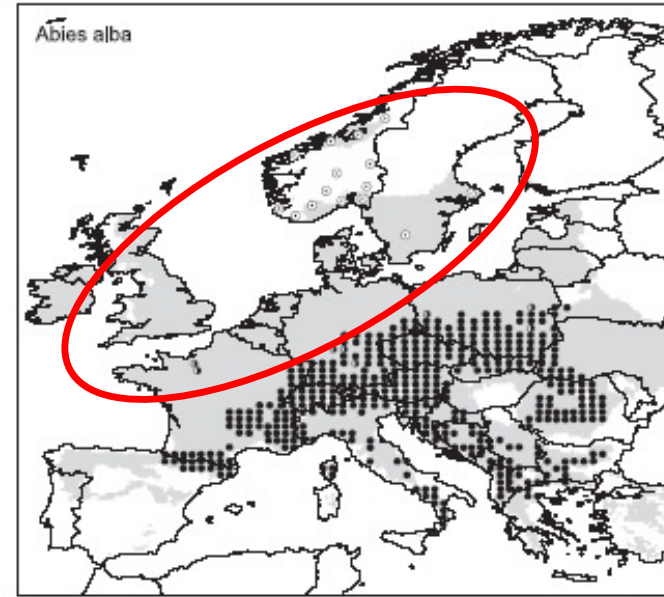

Pitfalls

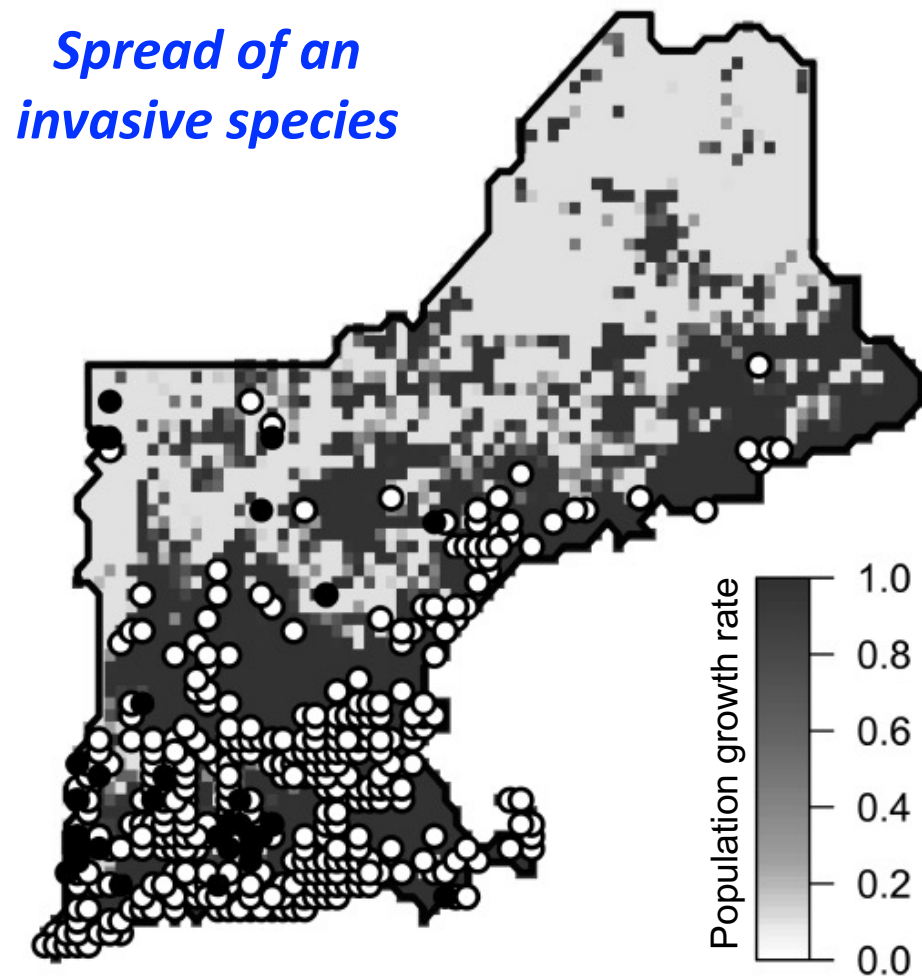

- Other (unmeasured) variables may be most important determinants of a species distribution
- A species may not be in *equilibrium* with the environment
 - Abundance (presence) is not highest where fitness is highest

Limited filling of the potential range in European tree species

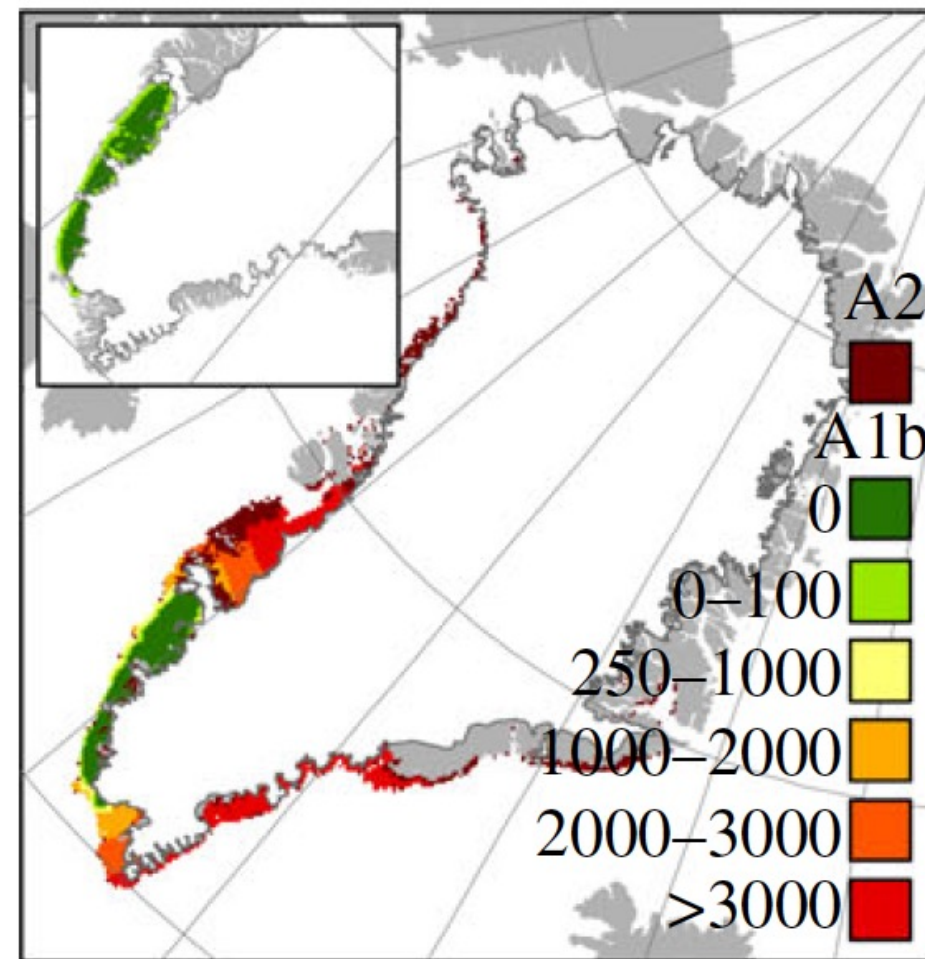

- Native
- Naturalized
- Potential Climatic range

Celastrus orbiculatus in Maine

*Predicting suitable areas under
climate change*

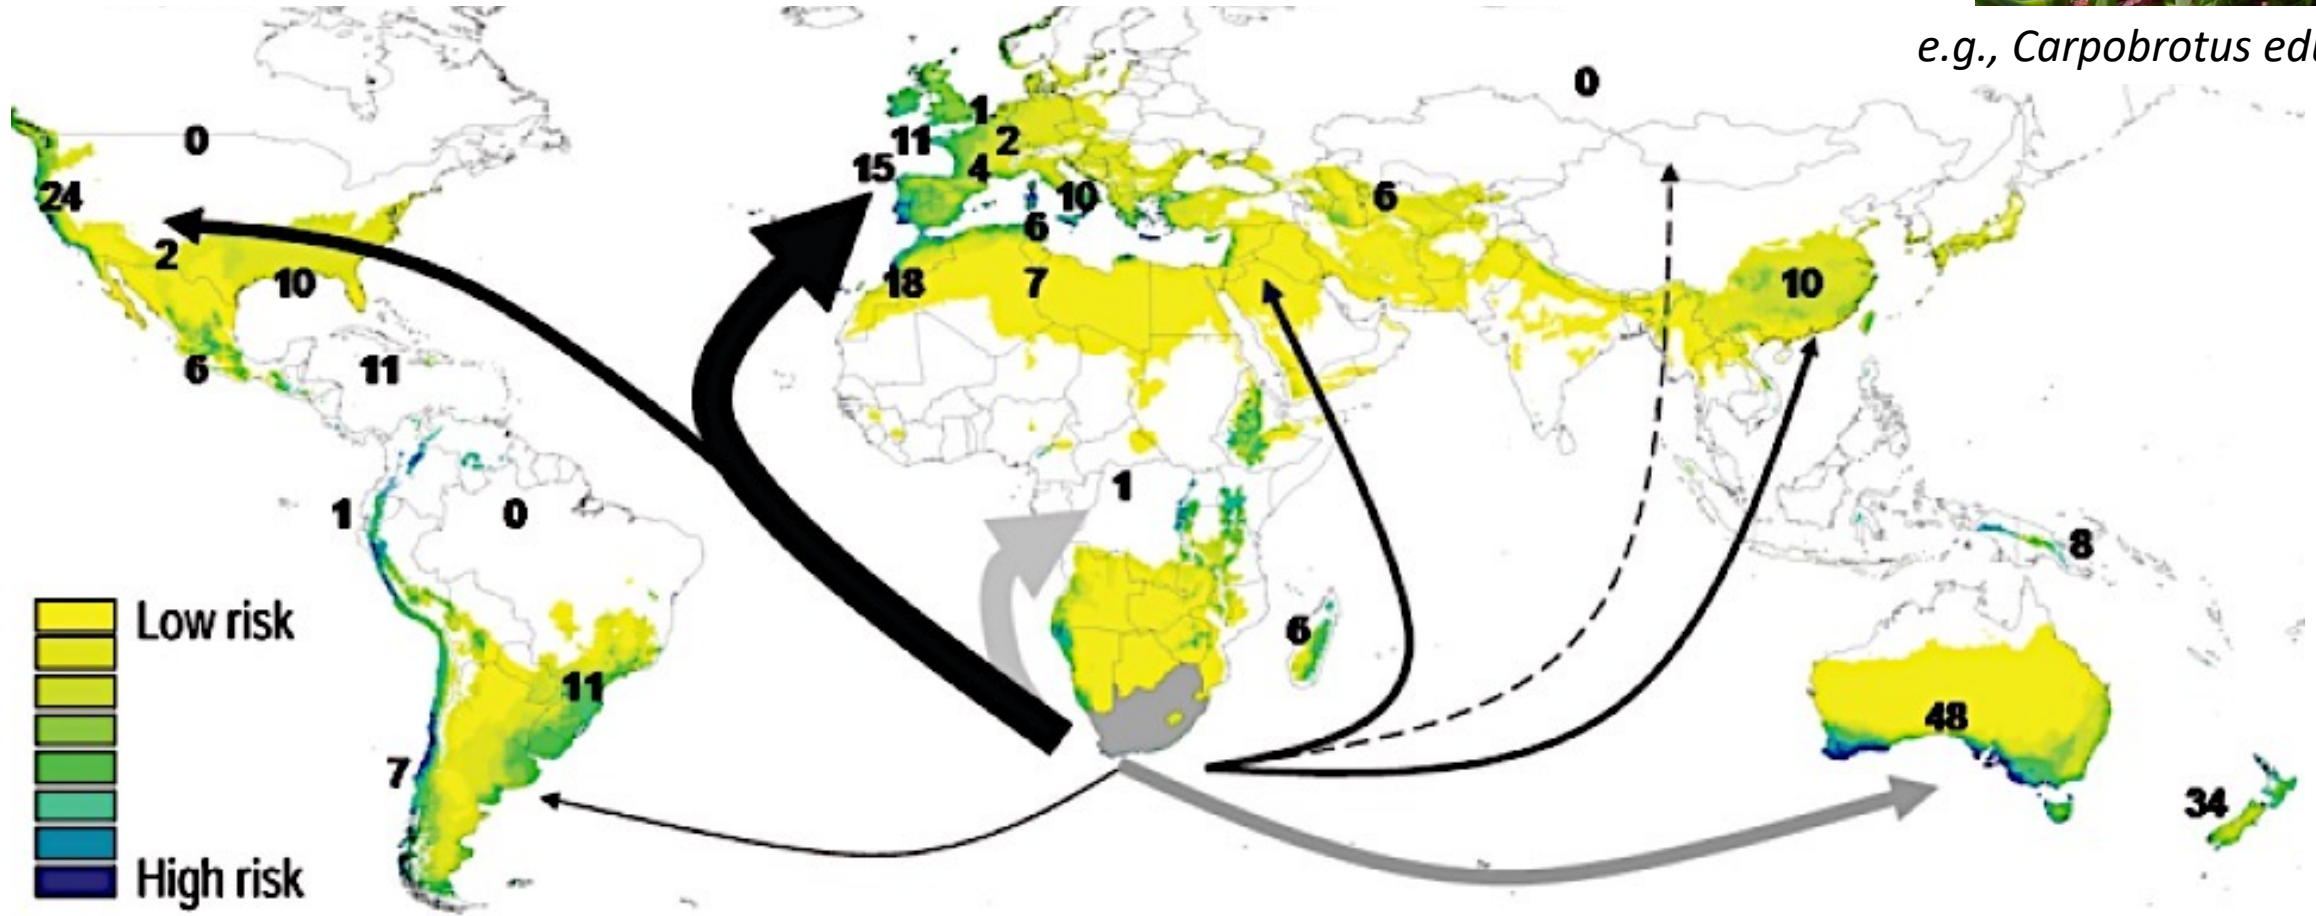

Suitable tree habitat in Greenland

Suitable habitat for South African ornamental plants predicts invasion success

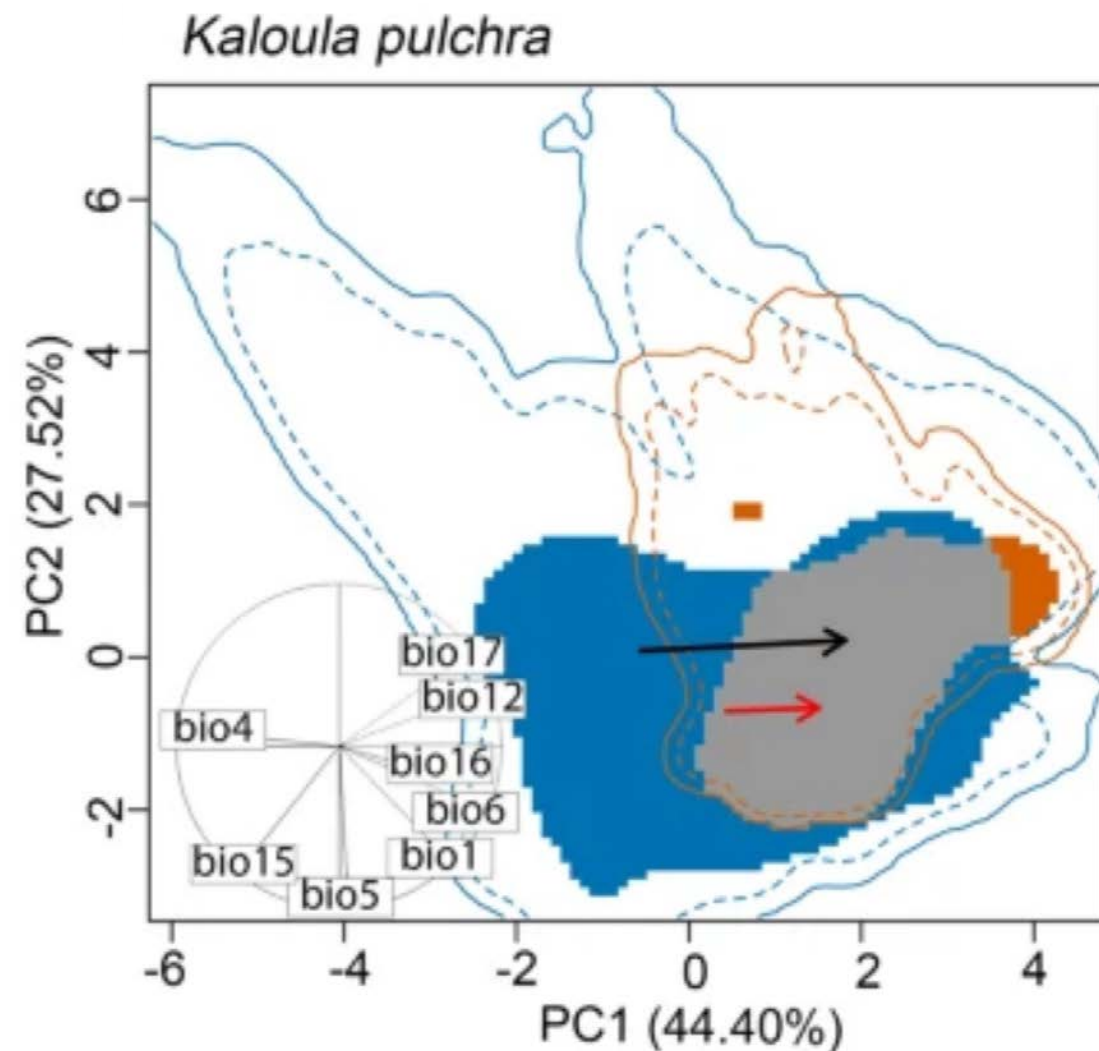

e.g., Carpobrotus edulis

Invasive species

OPEN Niche shifts and environmental non-equilibrium undermine the usefulness of ecological niche models for invasion risk assessments

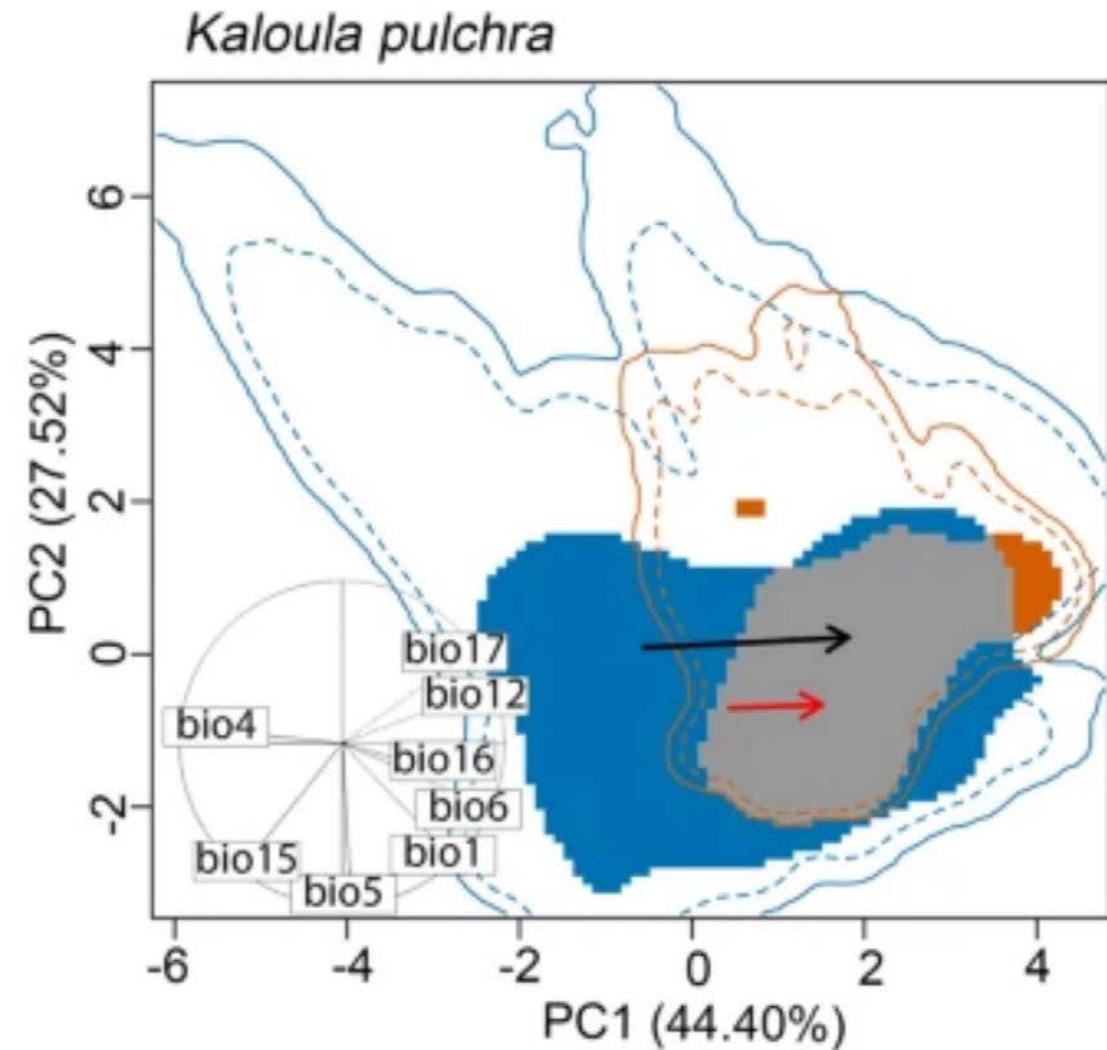

Arman N. Pili^{1,2,3}, Reid Tingley³, Emerson Y. Sy^{2,4}, Mae Lowe L. Diesmos^{2,5,6} & Arvin C. Diesmos^{1,2,7}

- Centroid shift from native to Philippine-invaded niche
- Centroid shift from native to Philippine range climate
- Climate niche in native range
- Climate niche in Philippine invaded-range
- Climate niche overlap

Invasive species

- Niche changes undermined the reciprocal transferability of ENMs calibrated using native and invaded range data.
- Our paper highlights the difficulty of predicting potential distributions given niche shifts and environmental non-equilibrium.
- We suggest calibrating ENMs with data from species' combined native and invaded ranges, and to regularly reassess niche changes and recalibrate ENMs as species' invasions progress.

- Centroid shift from native to Philippine-invaded niche
- Centroid shift from native to Philippine range climate
- Climate niche in native range
- Climate niche in Philippine invaded-range
- Climate niche overlap

Pitfalls

- Other (unmeasured) variables may be most important determinants of a species distribution
- A species may not be in *equilibrium* with the environment
 - Abundance (presence) is not highest where fitness is highest
- Are we using best practices?

Standards for distribution models in biodiversity assessments

Emerging infectious disease

Summary

- SDMs/ENMs are relevant for an *extremely broad range of applications*
- Some key assumptions are rarely met (e.g., environmental equilibrium)
- Best practices are ... not always ... used
- Yet, these types of models can be extremely useful (understanding, prediction, *communication*)
